Position of European Bioplastics

MARINE LITTER

The European Commission has identified marine litter as one of the main threats for the environment. Consequently, the Marine Strategy Framework Directive was designed and came into force in 2008. This Directive aims to achieve a Good Environmental Status (GES) of the EU's marine waters by 2020 and to protect the resource base on which marine-related economic and many social activities depend, including the provision that no damage should be caused by marine litter.

Plastics account for the largest share of marine litter. The key characteristics that make these plastic materials so valuable in the first place, such as stability and persistence, become the very reason that products made from these materials pose a significant problem for the environment at the end of their life cycle, unless they receive appropriate waste management treatment. When ending up in the seas or washed ashore, plastics turn into a threat to animals and other living organisms, especially due to ingestion or entanglement.

Marine debris originates from a variety of sources. Shipping and fishing activities are the predominant sea-based sources, whereas ineffectively managed landfills, public littering, and the careless disposal of waste in the environment are the main land-based sources of marine litter. If waste is deposited in open landfills, lightweight materials — and this especially accounts for plastics — can be blown away by wind or washed away by rain. This results in plastic waste ending up in rivers, lakes, and oceans. In order to minimise and ultimately prevent further pollution of the marine environment, European Bioplastics:

- considers the full implementation of EU waste legislation and an increase in the efficiency of waste management crucial;
- supports the gradual phase-out of landfiling for plastic products in Europe and appropriate measures to expand recycling and recovery of plastic waste;
- calls for stricter measures to combat littering, for example through fines, and supports more and better education about littering, which is often linked to a lack of information about the environmental consequences;
- calls for more research into biodegradation behaviour of materials and applications within marine environments and the establishment of standards, in order to determine applications that are likely to end up in marine environments, making marine biodegradability justified and necessary.

Littering should not be accepted as an unfortunate but inevitable fact for any kind of waste, neither on land nor at sea — including all varieties of plastics.

End-of-life options for bioplastics

European Bioplastics considers a sound and well-functioning, source-separated waste collection as one of the essential measures to fight marine litter. All types of waste should find their way to appropriate and controlled forms of waste management and recycling.

Bioplastics offer several benefits in well-functioning waste separation systems. Non-biodegradable materials like bio-based polyethylene (PE) or polyethylene terephthalate (PET) can, after multiple uses, be collected together with their fossil counterparts and delivered to suitable recycling or recovery streams.

---

4. The term bioplastics includes two main groups: 1. bio-based, non-biodegradable plastics, such as bio-based PE or bio-based PET; 2. compostable / biodegradable plastics. Bioplastics are plastics that are bio-based, biodegradable, or both.
For compostable plastic products, i.e. materials certified according to EN 13432, industrial composting and anaerobic digestion (AD) are the appropriate ways of (organic) recycling. Compostable biowaste collection bags have the added benefit of easing the pre-sorting in households and thus diverting biowaste from landfill into organic waste recovery systems. This means that they help to keep considerable quantities of waste out of landfill and inside the recovery and reuse loop. Therefore, mechanical and organic recycling of bioplastics should be supported. Incineration combined with energy recovery is, in the absence of organic recycling facilities, also an acceptable end-of-life option, generating partly renewable energy. In the case of bio-based plastics the material carbon loop is closed as the carbon dioxide taken from the atmosphere to produce the raw material is released again at the end of its product life during incineration.

**Biodegradable and compostable plastics** in marine environments

Currently, there is no international standard that appropriately defines the biodegradation of plastics in marine environments. However, a number of standardisation projects are in progress at ISO and ASTM level5,6. Even though plastics that are biodegradable according to established land-based treatment standards are not and never were intended as a solution to marine littering, the United Nations Environment Programme (UNEP) recognises that ‘biodegradability in seawater’ may be part of the solution6. EUBP fully supports the call of UNEP for more research into the biodegradation behaviour of existing material types and applications, as well as the determination of classes of applications where marine biodegradability can be considered an end-of-life option, and the establishment of standards by which to measure and affirm – or reject – claims of biodegradation in the respective marine environments very much in the same way as this has been achieved by the biodegradable industry for land-based uses and end-of-life scenarios.

European Bioplastics supports the development of a European standard on how to measure marine biodegradation in line with all pertinent research findings in the field of plastics in the marine environment. This standard should determine a defined time frame for the complete biodegradation9 of plastics for each of the different marine environments (eulittoral, sublittoral, and pelagic – from surface to deep sea – zones), which should be aligned with the set of requirements for other natural environments (e.g. soil5).

**About European Bioplastics**

European Bioplastics is the association representing the interests of the bioplastics industry along the entire value chain in Europe. Its members produce, refine, and distribute bioplastics, i.e. plastics that are either bio-based, biodegradable, or both. More information is available at [www.european-bioplastics.org](http://www.european-bioplastics.org).

---

1. Certain bioplastic materials are biodegradable/compostable and used in products where this characteristic offers added value. Compostable in this context means certified according to the harmonized European norm EN 13432. Such materials and products are suitable for the organic recycling, i.e. industrial composting and anaerobic digestion. EN 13432 certification gives no indication to what extent and within what timeframe a material will biodegrade in marine environments.

2. There are ASTM standards related to this topic. The ASTM standard D7801-05 (Standard Specification for Non-Floating Biodegradable Plastics in the Marine Environment) was withdrawn without replacement.

3. The European project Open-Bio conducts research into the marine biodegradation features of bio-based products. For more information see: [http://www.biobasedeconomy.eu](http://www.biobasedeconomy.eu)

4. UNEP, Marine plastic debris and microplastics – Global lessons and research to inspire action and guide policy change, 2016, pp. ii, 26, 133, 143, 176f.

5. Biodegradation according to EN13432 is considered to be complete, if at least 90% of the material have been converted into carbon dioxide (the remainder is due to the fact that besides carbon dioxide, water and biomass are produced during biodegradation, with carbon dioxide being the only part accurately measurable).

6. Belgian certifier Veritas sets the duration for soil biodegradation at a minimum of 90% in 2 years (the method refers to ISO 17356). A standard for biodegradation of mulch films is currently developed in CEN/TC 249/WG7.
